

3/23

## Homework 7

1.)

x	1	2	3	4
y	2	3	5	4

1.) Identify a good set of initial parameters  
 $(1, 2)$  &  $(4, 4) \rightarrow$  so it accounts for the entire data

$$m = \frac{4-2}{4-1} = \frac{2}{3}$$

$$\frac{y-2}{x-1} = \frac{2}{3}$$

$$3y - 6 = 2x - 2$$

$$3y = 2x + 4$$

$$y = \frac{2}{3}x + \frac{4}{3}$$

$$b = \frac{4}{3}$$

$$E(m, b) = \frac{1}{n} \sum_{i=1}^n |y_i - (mx_i + b)|$$

$$y = \frac{2}{3}x + \frac{4}{3} \quad | \quad y_{\text{actual}} - y_{\text{pred}} = y_i - (mx_i + b)$$

$$x = 1, y_{\text{actual}} = 2$$

$$y = \frac{2}{3} + \frac{4}{3} = \frac{6}{3} = 2$$

$$y_{\text{pred}} = 2$$

$$AE = 2 - 2 = 0$$

$$x = 2, y_{\text{actual}} = 3$$

$$y = \frac{2}{3}(2) + \frac{4}{3}$$

$$\frac{4}{3} + \frac{4}{3} = \frac{8}{3}$$

$$y_{\text{pred}} = \frac{8}{3}$$

$$AE = \frac{9}{3} - \frac{8}{3} = \frac{1}{3}$$

$$x = 3, y_{\text{actual}} = 5$$

$$y = \frac{2}{3}(3) + \frac{4}{3}$$

$$2 + \frac{4}{3} = \frac{6}{3} + \frac{4}{3} = \frac{10}{3}$$

$$y_{\text{pred}} = \frac{10}{3}$$

$$AE = 5 - \frac{10}{3} = \frac{15}{3} - \frac{10}{3} = \frac{5}{3}$$

$$x=4 \quad y_{\text{actual}}=4$$

$$y = 2/3 x + 4/3 = 2/3 (4) + 4/3 = 12/3 = 4$$

$$y_{\text{pred}}=4 \quad AE = 4 - 4 = 0$$

$$\sum MAE$$

$$0 + 1/3 + 5/3 + 0 = 6/3 = 2$$

$$E(2/3, 4/3) = 1/4 \times 2 = 0.5 \rightarrow MAE = 0.5$$

$$3.) \frac{dE}{dm} = -1/n \sum_{i=1}^n \text{sign}(y_i - (mx_i + b)) \cdot x_i$$

$$\frac{dE}{db} = -1/n \sum_{i=1}^n \text{sign}(y_i - (mx_i + b))$$

$$x=1 : 2-2=0 \quad \text{sign}(0)=0$$

$$x=2 : 3-8/3=1/3 \quad \text{sign}(1/3)=1$$

$$x=3 : 5-10/3=5/3, \quad \text{sign}(5/3)=1$$

$$x=4 : 4-4=0, \quad \text{sign}(0)=0$$

$$\frac{dE}{dm} = -1/4 (0 \cdot 1 + 1 \cdot 2 + 1 \cdot 3 + 0 \cdot 4)$$

$$\frac{dE}{dm} = -5/4$$

$$\frac{dE}{db} = -\frac{1}{4} (0+1+1+0)$$

$$-\frac{1}{4} \times 2 = -\frac{1}{2}$$

$$L = 0.07$$

$$m - L \frac{dE}{dm} = \frac{2}{3} - 0.07 \times \left(-\frac{5}{4}\right) = 0.75$$

$$b - L \frac{dE}{db} = \frac{4}{3} - 0.07 \left(-\frac{1}{2}\right) = 1.37$$

Adjusted model:

$$y = 0.75x + 1.37$$

$$x=1 \quad y_{\text{actual}} = 2:$$

$$y = 0.75 + 1.37$$

$$y_{\text{pred}} = 2.12$$

$$AE = |2 - 2.12| = 0.12$$

$$x=2 \quad y_{\text{actual}} = 3$$

$$y = 0.75(2) + 1.37$$

$$y_{\text{pred}} = 2.87$$

$$3 - 2.87 = 0.13$$

$$x=3 \quad y_{\text{actual}} = 5$$

$$y = 0.75(3) + 1.37 = 3.62$$

$$5 - 3.62 = AE = 1.38$$

$$x = 4 \quad y_{\text{actual}} = 4$$

$$y_{\text{pred}_4} = 0.75(4) + 1.37$$

$$y_{\text{pred}_4} = 4.37$$

$$|4 - 4.37| = 0.37$$

$$0.12 + 0.13 + 1.38 + 0.37 = 2$$

$$\frac{1}{4} \times 2 = 0.5$$

The MAE remains 0.5 which is the same as initial error. Suggesting that the learning ratio might be too small to make a significant change
